# Ross Sea Cloud Satellite Observations

## Objectives

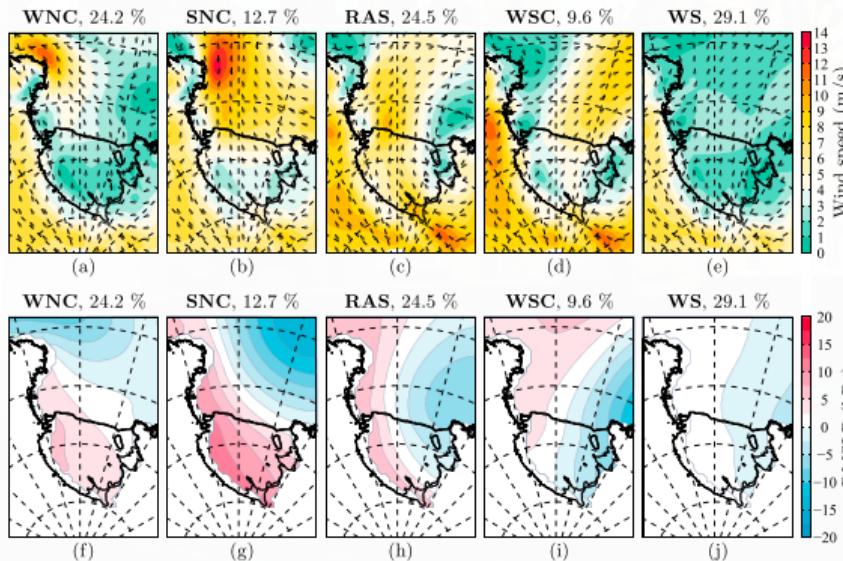

- Establish cloud climatology (\*) over RS & RIS as seen by CloudSat/CALIPSO
- Follow-up on work by Coggins et al. (2016) on synoptic classification in the region
- Determine how cloud vertical distribution and properties vary with seasons and synoptic regimes

# Ross Sea Cloud Satellite Observations

## Coggins regimes

Weak Northern Cyclonic (WNC), Strong Northern Cyclonic (SNC), Ross Ice Shelf airstream (RAS),  
Weak Southern Cyclonic (WSC), Weak Synoptic (WS)

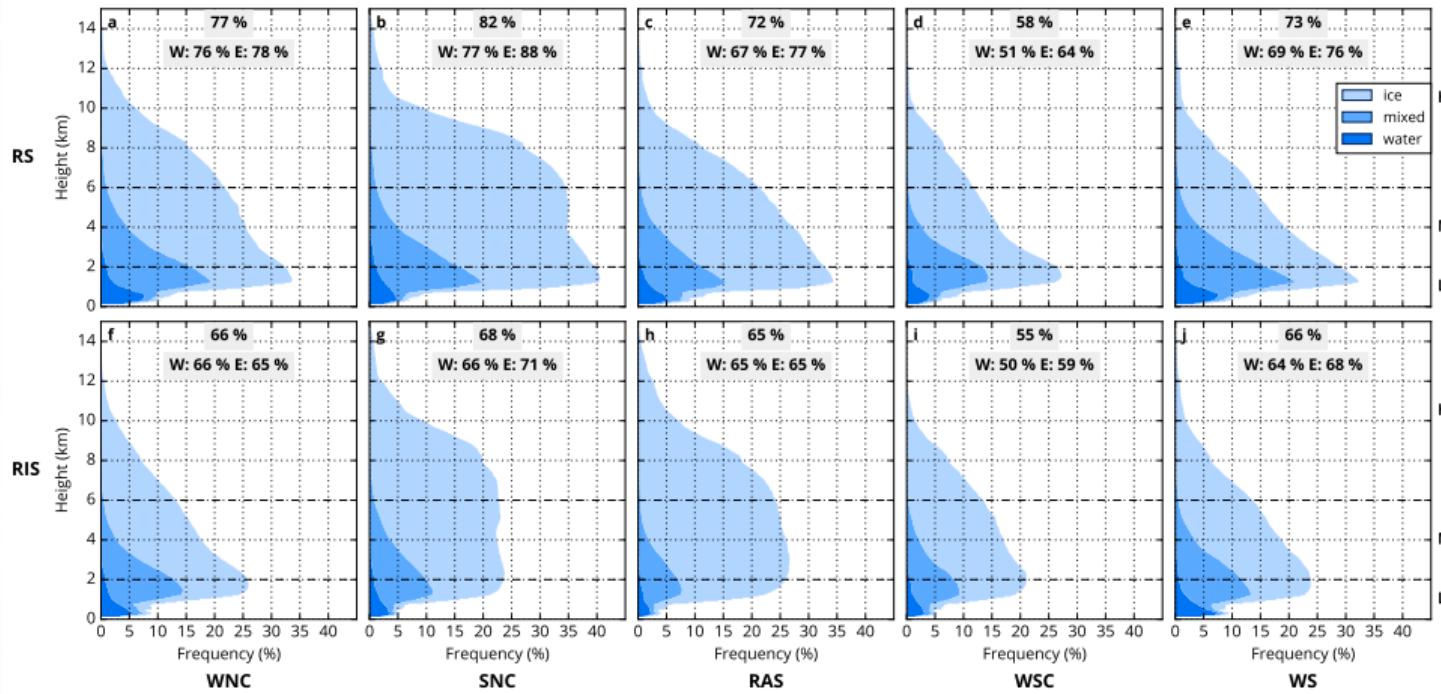

# Ross Sea Cloud Satellite Observations

## CloudSat-CALIPSO datasets

- Datasets:
  - 2B-GEOPROF-LIDAR P\_R04 (2006–2011)
  - 2B-CLDCLASS-LIDAR P\_R04 (2007–2011)
  - 2B-GEOPROF-LIDAR P\_R05 (2006–2016)

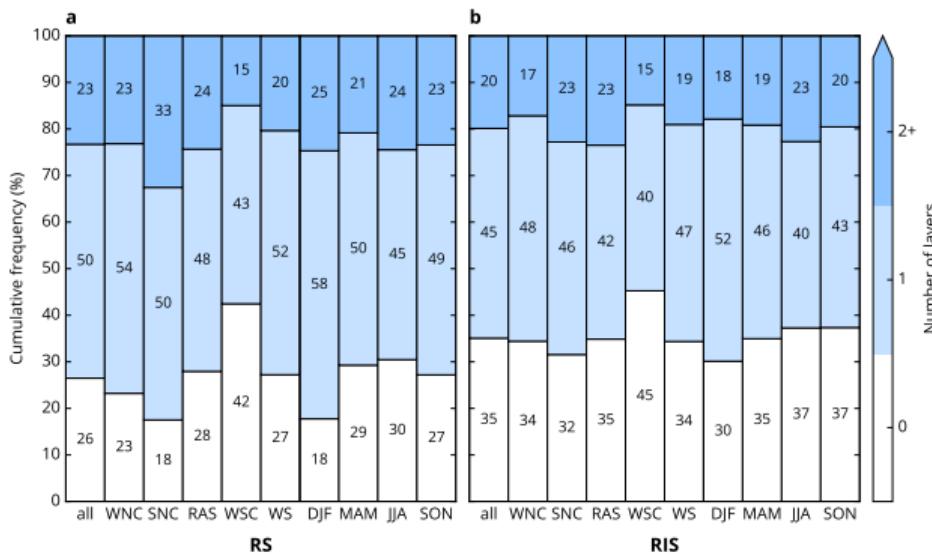

# Ross Sea Cloud Satellite Observations

## Ice shelf vs. sea

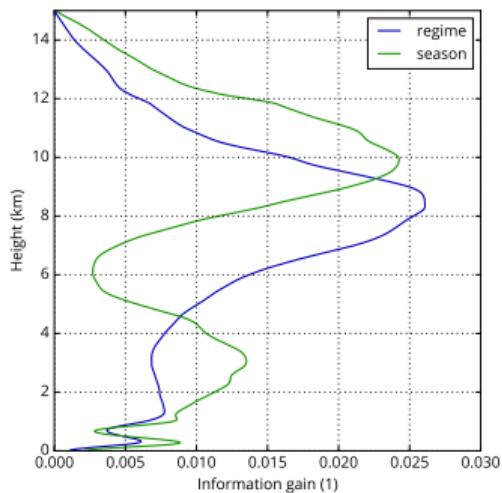

# Ross Sea Cloud Satellite Observations

What is the role of seasons compared to weather regimes

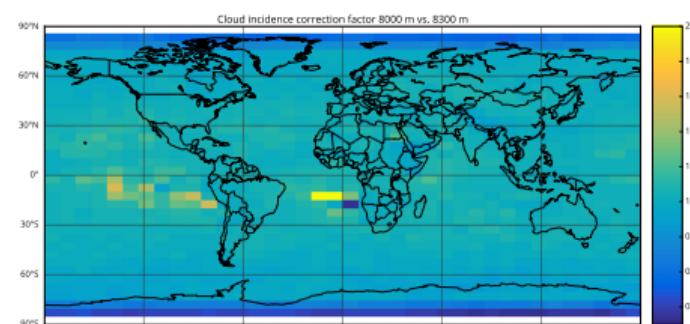

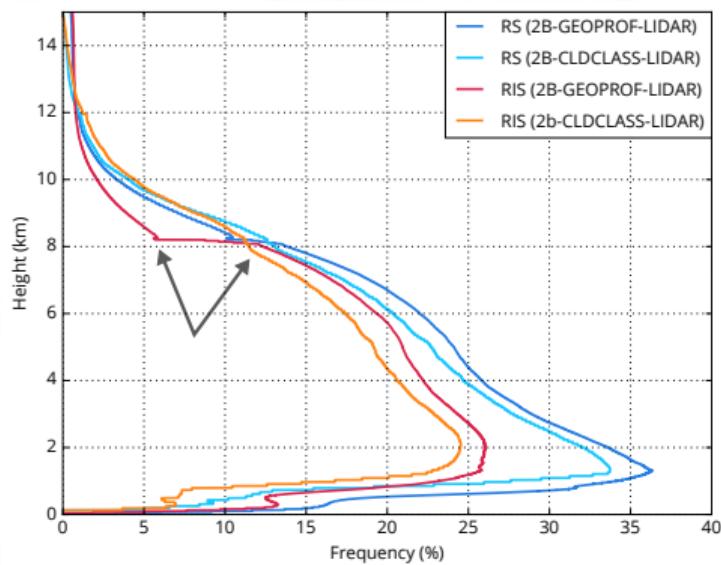

Information gain (Ross Ice Shelf, 2007-2010, 2B-CLDCLASS)

# Ross Sea Cloud Satellite Observations

## 2B-GEOPROF-LIDAR P\_R04 data issues

Ratio of cloud occurrence at 8.3 km rel. to 8 km

## Objectives

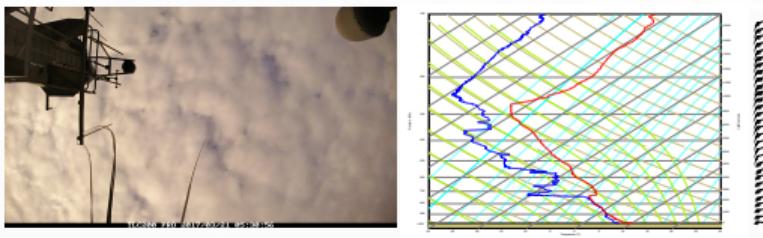

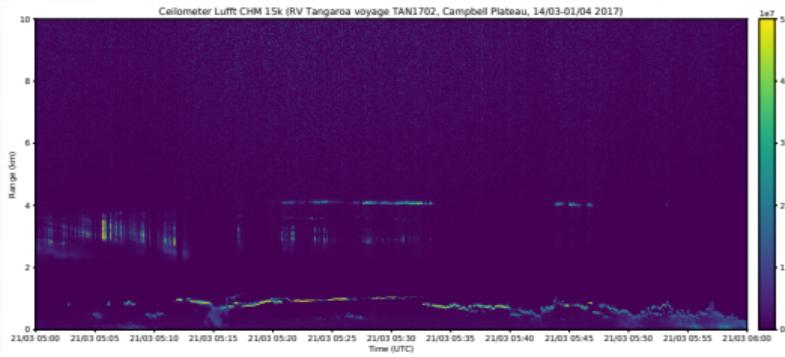

- Create a comprehensive multi-year dataset of ground-based and in-situ observations of C&A in the SO
- Use them for NZESM evaluation and improve C&A parametrisation in the SO

## Instruments

- Ceilometer: Lufft CHM 15k,  
Vaisala CL51
- Radar: Metek MRR-2
- Radiosondes
- Sky-viewing camera
- AWS, pyranometers
- Aerosols (NIWA)

## Complementing observations

## Plans

- Complete dataset:
  - All deployments
  - Well-documented
  - Standard data formats: NetCDF/HDF5 (CF)
  - Publicly available

## Objectives

- Evaluation of NZESM using ground and in-situ observations of C&A in the Southern Ocean
- Use the COSP satellite simulator developed by CFMIP

## Observations

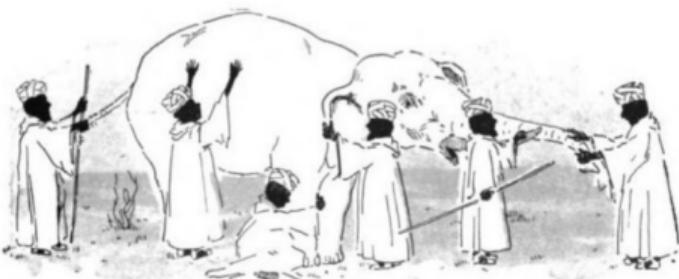

- Ground-based and in-situ:
  - IOP
  - ARM
- Satellite:
  - Passive VIS & IR: ISCCP, MODIS, MISR, ...
  - Radiative budget: CERES
  - Active: CloudSat, CALIPSO (possibly GLAS, CATS, EarthCARE)
  - Passive microwave (total column water): AMSR-E (Aqua), AMSR-2 (GCOM-W1), SSM/I (DMSP), MIS (NPOESS), TMI (TRMM)

## Simulators

- ACTSIM – lidar simulator
  - Input: water/ice mixing ratio (convective and stratiform), effective radius of cloud/ice particles
  - Output: backscatter
- QuickBeam – radar (CloudSat) simulator

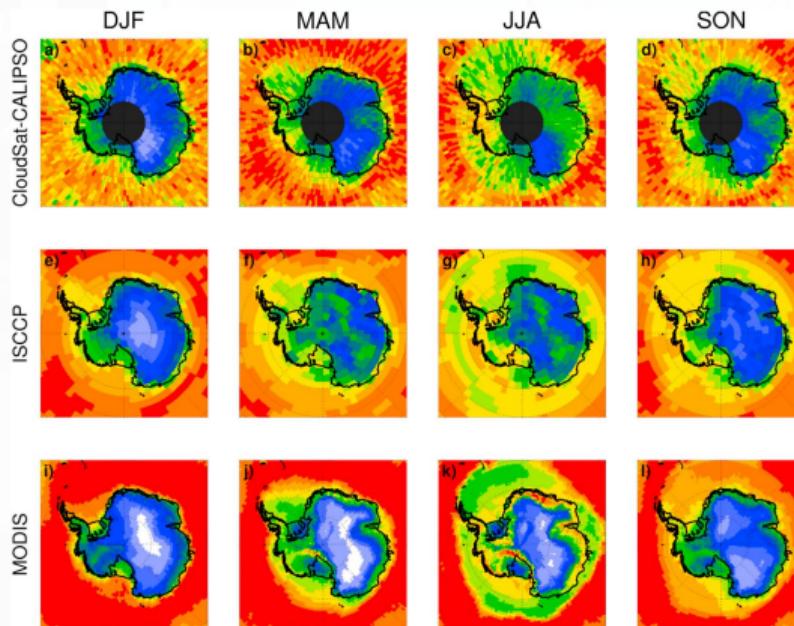

## Comparing the same thing

- Analogy: 'Blind men and an elephant'
- Same physical quantity
- Resolution problem
- Spatial/temporal co-location
- Choice of False Alarm Ratio

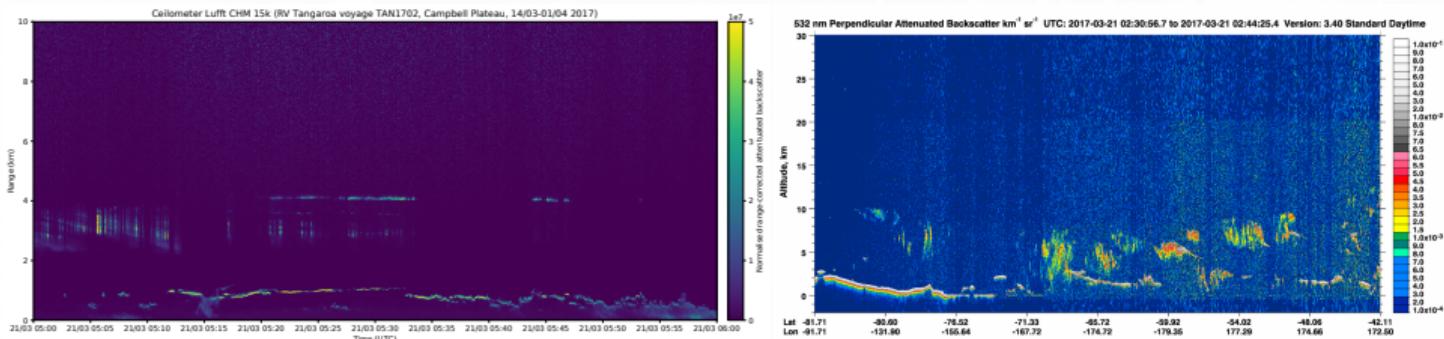

# COSP

## Mean seasonal cloud fraction (Bromwich et al., 2012)

## Ceilometer (IOP) vs. CALIPSO

- 2017-03-21 05:00 UTC, Campbell Plateau

# COSP

## Model vs. observation vs. reality

### Model

Cloud vertical distribution, fraction, phase, liquid/ice mixing ratio  
Droplet size distribution/effective radius  
Cloud subsampling (McICA) and overlap  
Radiative transfer approximations  
Cloud types: convective, stratus  
Temperature profile and gas concentration

### Observation

Cloud fraction, top, base, optical depth, geometric depth  
Backscatter, radar reflectivity  
Cloud types: Cu, St, Sc, DC, Ci  
Temperature, humidity, pressure profile  
Affected by error (type I, II, Gaussian, ...), bias, limited view, coverage, spatial/temporal res., spectral res.

### Reality

Cloud droplet and ice crystal distribution  
Aerosol distribution  
Temperature profile and gas concentration

# COSP

## NZESM

- Nudged
- Unnudged
- COSP:
  - From model fields to pseudo-observations to derived properties

## The other way round

- Assimilation
- From observations to model fields (with proper uncertainty evaluation)
- Can we put multiple observations together?

## Upscaling

- Correlating ground-based observations with satellite observations
- Deriving pseudo ground-based observations based on satellite observations:
  - If we know what the satellite instruments sees, what would ground-based instruments be likely to see?

## Challenges

- Subsampling (cloud resolving model)
- Nudging
- Small and irregular temporal and spatial coverage
- From backscatter to cloud layers

**Thank you**
